

NEW PLANNING DECK

Idea Planning + Indicator Playbook

Use this deck to shape new product ideas, call out what still needs polish, and teach indicators as simple chart context instead of magic buttons.

Decision rule

A Planifier idea should become a practice plan only when the learner can point to the chart, explain the indicator context, and name the condition that would prove the idea wrong.

Plan ideas

Market, timeframe, thesis, level, invalidation.

Find gaps

Where text, layout, or workflow gets in the way.

Teach context

Indicators explain evidence. Price still leads.

PLANNING PRINCIPLE

A new idea should enter as a testable question, not a prediction.

The product should keep the user focused on evidence, invalidation, and review. That makes future saved trades useful instead of just stored screenshots.

Market

Which pair, stock, or index is being studied?

Chart read

Trend, level, current price location.

Indicator clue

What context does the indicator add?

Practice rule

Entry idea, target, risk, invalidation.

Review

What happened and what did I learn?

Idea prompt

I am studying [market] on [timeframe] because price is near [level]. The indicator says [context]. I am wrong if [condition].

Quality check

Can I explain it in one sentence? Can I show the level on the chart? Do I know where the idea fails?

Product implication

The builder should ask fewer vague questions and more chart-specific ones.

NEW IDEA INTAKE

Make pair selection and chart basics visible before the user writes the plan.

This helps beginners stop guessing at random markets and start comparing one chart setup against another.

BTC/USD

ETH/USD

EUR/USD

AAPL

SPY

GOLD

Pair dropdown should show

Last price
Percent change
Asset class
Beginner hint: crypto moves differently than forex, stocks, or gold
Default timeframe

Charting basics to ask

What is trend doing?
Where is support/resistance?
Is price near the middle or edge?
Is volume confirming?
What indicator would help here?

Usability gap

The user should not need to know what O/H/L/C means. Label it as Open, High, Low, Close until learning mode is off.

Planning output

Selected market + timeframe + current price should flow into the plan automatically so the user does not copy numbers by hand.

PRICE FIRST

The beginner flow should teach a fixed read order before any indicator is introduced.

Indicators are useful only after the chart has a location and a question.

01

Trend

Are highs/lows rising, falling, or mixed?

02

Location

Is price at support, resistance, breakout, or middle?

03

Candle behavior

Is the candle rejecting, breaking, or drifting?

04

Volume

Did participation expand or fade?

05

Indicator

Use one indicator to answer one specific question.

INDICATOR CARDS

Every indicator needs the same beginner explanation structure.

This keeps learning mode useful without repeating the same sentence before every line of text.

Measures

What the indicator is actually calculating in plain English.

Useful when

The market condition where this indicator helps most.

Watch out

Where it fails, lags, or creates false confidence.

Confirm with

The chart evidence that should agree with it.

Beginner question

One question the learner can answer before moving on.

Core wording

An indicator explains context. It does not approve a trade. Price location, risk, and invalidation still decide whether the plan is worth practicing.

MOVING AVERAGES

Use MA/EMA to explain trend direction, slope, and pullback context.

Best beginner use: is price above/below the average, and is the average rising or falling?

What it measures

Average price over a chosen number of candles. EMA reacts faster than SMA.

Beginner use

Trend context: rising average plus pullback can be cleaner than chasing a candle after it already moved.

Common trap

Moving averages lag. A crossover after a big move can be late evidence, not a fresh idea.

RSI

Use RSI to study momentum, exhaustion, and divergence without treating 70/30 as automatic.

Best beginner use: ask whether momentum agrees with the price move near a real level.

What it measures

Recent momentum: how strong gains are compared with losses.

Good question

Is price making a new high while RSI is weaker? That can warn momentum is fading.

Common trap

RSI can stay high in strong uptrends and low in strong downtrends. It is context, not a reversal button.

VOLUME + VWAP

Use volume to check participation and VWAP to understand intraday fair-value pressure.

These are practical because they help answer whether a move has support behind it.

Volume asks

Did more participation show up on the break, retest, or rejection?

VWAP asks

Is price reclaiming fair value, rejecting it, or stretched far away from it?

Beginner trap

Low volume breakouts and late chases above VWAP can look clean in hindsight but be low quality in real time.

MACD + ATR

Use MACD for momentum shifts and ATR for volatility-aware plan sizing.

These indicators are stronger as planning tools than entry permission tools.

MACD: momentum shift

Measures the relationship between fast and slow moving averages.
Beginner use: watch whether momentum is expanding or fading near a level. Trap: late crossovers after price already moved.

ATR: volatility and room

Measures average candle range. Beginner use: avoid placing the wrong-if line so tight that normal volatility knocks it out. Trap: ATR does not predict direction.

ATR RANGE

Product idea

Indicator cards should show what it measures, when it helps, when it fails, and one beginner question tied to the current chart.

BOTTOM EXAMPLE STRIP

Historical examples should teach pattern recognition by showing before, during, and after states.

Each example should include the indicator state so the user can compare context, not memorize outcomes.

Breakout retest

MA rising, volume expands

Did support turn into acceptance?

Learner action: compare the chart level, price reaction, and indicator clue before reading the outcome.

Support failure

RSI weak, volume expands down

Did the wrong-if trigger clearly?

Learner action: compare the chart level, price reaction, and indicator clue before reading the outcome.

Range chop

VWAP flat, ATR compressing

Is patience better than forcing a plan?

Learner action: compare the chart level, price reaction, and indicator clue before reading the outcome.

POLISH BACKLOG

The next improvements should reduce guessing and make the chart feel more like a simple TradingView workspace.

Focus the UI on chart context, clear labels, useful defaults, and fewer repeated beginner reminders.

AREA	FIX	IMPACT
Pair picker	Show asset, last price, change, and timeframe defaults	High
Current price tags	Label actual price next to each key line	High
Indicator cards	Explain MA, RSI, Volume, VWAP, MACD, ATR in learning mode	High
Historical strip	Show example snapshots below the workspace	Medium
Saved trades	Paid users can save, tag, and review completed practice ideas	Medium
Text restraint	Say the core beginner warning only where it matters	High

BUILD ORDER

Ship the planning tools in the order that removes the most learner confusion first.

This keeps the app useful while the bigger paid saved-trade system is still being designed.

1

Pair dropdown + price labels

Choose market cleanly and understand O/H/L/C/current price without guessing.

2

Indicator explainer drawer

One card per indicator with measures, useful when, watch out, confirm with, beginner question.

3

Historical example strip

Show comparable past setups below the chart with indicator state and outcome.

4

Saved practice trades

Paid feature: save plan, snapshot, tags, result, notes, and lessons learned.

5

Idea quality score

Flag missing invalidation, weak location, no indicator question, or unclear review prompt.

Operating principle

Make every plan explain why it exists, what would prove it wrong, and what the learner should review later.
